

# Standard Chiller Modular HP 1/4 Generic /Bitzer screw compressor and CAREL valve

Application program for  $pCO^1$ ,  $pCO^2$ ,  $pCO^3$ 

# User manual

Manual Version: 1.5 dated 22/02/09 Program code: FLSTDmMSBE

# We wish to save you time and money!

We can assure you that the thorough reading of this manual will guarantee correct installation and safe use of the product described.

# **IMPORTANT WARNINGS**

BEFORE INSTALLING OR HANDLING THE DEVICE PLEASE CAREFULLY READ AND FOLLOW THE INSTRUCTIONS DESCRIBED IN THIS MANUAL.

# The device this software refers to was built to operate risk free for the intended purposes, providing:

software installation, programming, operational control and maintenance must be carried out by qualified personnel according to the instructions in this manual; all the conditions prescribed and contained in the installation and use manual of the application in question are observed.

All other uses and modifications made to the device which are not authorised by the manufacturer are considered incorrect. Liability for injury or damage caused by the incorrect use of the device lies exclusively with the user.

# INDEX

| 1  | APPLICATIONS AND FUNCTIONS PERFORMED BY THE SOFTWARE |  |      |  |
|----|--|--|------|--|
| 2  |  |  |      |  |

# 1 Applications and functions performed by the software

# Type of control unit

AIR / WATER CHILLER

- Chiller only
- Chiller + Heat pump
- Chiller + Freecooling

# WATER / WATER CHILLER

- Chiller only
- Chiller + Heat pump with gas reversing
- Chiller + Heat pump with water reversing

# Type of control

 $\label{eq:proportional} Proportional ~+~ integral control on the evaporator water inlet temperature probe. \\ Time control of the neutral zone on the evaporator water outlet temperature probe. \\$ 

# Types of compressors

Screw compressors with 4 capacity control steps Screw compressors with continuous duty capacity control. Bitzer screw compressors

## Maximum number of compressors

From 1 to 4 with a maximum of 4 capacity control steps(1 compressor for every pCO\*)From 1 to 4 with continuous duty capacity control.(1 compressor for every pCO\*)

# Compressor duty call rotation

Rotation of all compressors to FIFO logic for stepped and continuous duty capacity control.

# Condensation

Condensation can be performed according to temperature, pressure or ON/OFF Fan management in stepped mode or with 0/10 Volt proportional signal

# Type of defrosting

Overall defrosting of all pCO units connected to network: Independent/Simultaneous/Separate

# Safety devices for all refrigerating circuits

High pressure (pressure switch/transducer) Low pressure (pressure switch/transducer) Oil/Oil Level differential pressure switch Compressor thermal cutout Thermal cutout for condensation fan High delivery temperature to compressor Pressure differential alarm Antifreeze alarm Low superheat alarm (only with EVD driver enabled)

## System Safety devices

Serious alarm input (shuts down entire unit) Flow-switch input for evaporator/condenser (shuts down entire unit) Pump thermal cutout input (shuts down entire unit) Remote ON/OFF input. Check electronic expansion valve driver operating status (only with EVD driver enabled)

## Other functions

Alarms logging Built-in terminal management (on pCO<sup>2</sup>-pCO<sup>3</sup> only) Management of ratiometric probes for pressure control (on pCO<sup>1</sup>-pCO<sup>3</sup> only) EVD driver for piloting the EXV valve. Multi-language management.

## Accessories

Supervision with serial card RS485 (CAREL or MODBUS protocol) Supervision with LON serial board

## Compatible hardware

pC0<sup>1</sup> Medium, pC0<sup>2</sup> Medium and pC0<sup>2</sup> Medium built-in, pC0<sup>3</sup> Medium and pC0<sup>3</sup> Medium built-in.

# 2 The user terminal

# 2.1 Type and operation

Three different types of user terminal can be connected:

- 1. PGD0/semigraphic/6 buttons/4 rows 20 columns/connection via telephone cable
- 2. LCD/15 buttons/4 rows 20 columns/connection via telephone cable
- 3. Built-in display/6 buttons/4 rows 20 columns (only on pCO<sup>2</sup> pCO<sup>3</sup> board)

The user terminal, whichever is used, can perform all the operations allowed by the application program installed. The user terminal displays the operating conditions of the unit.

The terminal can be used to modify all the unit operating parameters, in real time. The user terminal is not required for the correct operation of the unit.

# 2.2 LEDs

#### 1.1.1 PGD0 terminal with 6 buttons

| LEDs                      | Colour | Description  |
|---------------------------|--------|--|
| [Arrow] button<br>(Alarm) | Red    | On – One or more alarm conditions have occurred                      |
| PRG button                | Yellow | On – Unit on<br>Flashing – Unit off from supervisor or digital input |

All the LEDs not described and located underneath the remaining 4 buttons indicate that the instrument is powered. Together with the backlighting of the display, these will be switched off if no button is pressed on the keypad for 5 minutes.

#### 2.2.1 LCD terminal with 15 buttons

Each button has a green LED indicating the specific group of parameters selected during the operations to display/modify the operating parameters. The silicone rubber buttons have three different coloured LEDs, whose meaning is specified in the following table:

| LEDs             | Colour | Description  |
|------------------|--------|--|
| [ On/Off ]       | Green  | On – Unit on   |
| button           |        | Flashing – Unit off from supervisor or digital input |
| [ Alarm ] button | Red    | On – One or more alarm conditions have occurred      |
| [Enter] button   | Yellow | On – Instrument correctly powered                    |

#### 2.2.2 Built-In terminal with 6 buttons

Given the number of buttons and LEDs available, these have general meanings, as described below:

| LEDs                       | Colour | Description  |
|----------------------------|--------|--|
| [Arr ] button<br>(Alarm)   | Red    | On – One or more alarm conditions have occurred      |
| [ ←] button (Enter) Yellow |        | On – Unit on   |
|                            |        | Flashing – Unit off from supervisor or digital input |
| [Prg] button               | Green  | On – Displaying/modifying the operating parameters   |
| [Esc] button               | Green  | On – Main menu parameters displayed                  |

# 2.3 Use of the buttons

# 2.3.1 PGD0 terminal with 6 buttons

| Button      | Description  |
|-------------|--|
| ALARM       | displays the alarms, mutes the buzzer and deletes the active alarms  |
| UP          | if the cursor is in the home position (top left corner), scrolls up the screens in the same group; if the cursor is in a setting field, increases the value                                |
| DOWN        | if the cursor is in the home position (top left corner), scrolls down the screens in the same group; if the cursor is in a setting field, decreases the value                              |
| ENTER       | used to move the cursor from the home position (top left corner) to the setting fields, in the setting fields confirms the set value and moves to the next parameter                       |
| PRG         | accesses the menu for selecting the group of parameters to be displayed/modified (access to the parameters is confirmed by pressing the [Enter] button)                                    |
| PRG + ENTER | In pLAN applications with more than one board connected in the network and a shared user terminal, switches the user terminal between the different units to display/modify the parameters |
| ESC + ENTER | Pressed at the same time for 20 seconds access the screen for switching the unit On/Off  |

# 2.3.2 LCD terminal with 15 buttons

| Button     |                       | Description   |  |  |
|------------|-----------------------|---|--|--|
| Menu       | MENU                  | From any point of the user interface (with the exception of the manufacturer group of parameters) returns to the Main menu screen (M0) displaying the unit status, readings of the control probes and operating mode.<br>In the group of manufacturer parameters, organised into nested sub-groups, returns to screen for selecting the parameters. |  |  |
| R          | MAINTENANCE           | Goes to the first screen of Maintenance parameters (A0)<br>The maintenance parameters are used to check the operating status of devices and the probes, control maintenance,<br>calibrate the readings and run manual operations  |  |  |
| G          | PRINTER               | Temporary display of the pLAN address of the current board  |  |  |
| 110        | INPUTS<br>AND OUTPUTS | Goes to the first screen of I/O parameters (IO)<br>The I/O parameters display the status of the inputs and the outputs on the board   |  |  |
| $\bigcirc$ | CLOCK                 | Goes to the first screen of Clock parameters (K0)<br>The Clock parameters are used to display/set the operating parameters for the clock board and activate the time<br>bands   |  |  |

Standard Chiller/HP modulare per compressore a vite Generico/Bitzer con driver CAREL

| Button     |           | Description  |
|------------|-----------|--|
| Set        | SET POINT | Goes to the first screen of Set point parameters (S0).<br>The Set point parameters are used to display/modify the unit working set point within the limits defined in the<br>configuration   |
| Prg        | PROGRAM   | Goes to the screen for entering the user password (P0)<br>The user parameters are used to modify the unit operating mode   |
| Menu + Prg | MENU+PROG | Goes to the screen for entering the manufacturer password (Z0)<br>The manufacturer parameters are used to configure the unit in terms of the number and type of devices connected,<br>enable specific accessories or special functions |
| ?          | INFO      | In pLAN applications with more than one board connected in the network and a shared user terminal, switches the user terminal between the different units to display/modify the parameters   |
|            | RED       | With the unit off, if the chiller + heat pump configuration is featured, enables heating operation   |
|            | BLUE      | With the unit off, if the chiller + heat pump configuration is featured, enables cooling operation   |

# Silicon rubber buttons

|   | Button   | Description   |
|---|----------|---|
| 1 | ON/OFF   | switches the unit on/off  |
| 2 | ALARM    | displays the alarms, mutes the buzzer and deletes the active alarms   |
| 3 | UP ARROW | if the cursor is in the home position (top left corner), scrolls up the screens in the same group; if the cursor is in a setting field, increases the value |
| 4 | DOWN     | if the cursor is in the home position (top left corner), scrolls down the screens in the same group; if the cursor is in a setting field, decreases the     |
|   | ARROW    | value   |
| 5 | ENTER    | used to move the cursor from the home position (top left corner) to the setting fields, in the setting fields confirms the set value and moves to the       |
|   |          | next parameter  |

## 2.3.3 Built-in 6 button terminal

| pGD user interface |                           | ALARM | PRG | ESC    |
|--------------------|---------------------------|-------|-----|--------|
|                    | Prg Esc                   |       |     |        |
|                    | AREL<br>(+) (+) (+) (AREL | DOWN  | UP  | ENTER  |
|                    |                           | Down  | 01  | LIVILI |

| Button      | Description   |
|-------------|---|
| ALARM       | displays the alarms, mutes the buzzer and deletes the active alarms   |
| UP          | if the cursor is in the home position (top left corner), scrolls up the screens in the same group; if the cursor is in a setting field, increases the |
|             | value   |
| DOWN        | if the cursor is in the home position (top left corner), scrolls down the screens in the same group; if the cursor is in a setting field, decreases   |
|             | the value   |
| ENTER       | used to move the cursor from the home position (top left corner) to the setting fields, in the setting fields confirms the set value and moves        |
|             | to the next parameter   |
| PRG         | accesses the menu for selecting the group of parameters to be displayed/modified (access to the parameters is confirmed by pressing the               |
|             | [Enter] button)   |
| PRG + ENTER | Temporary display of the board pLAN serial address  |
| ESC + ENTER | Pressed at the same time for 20 seconds access the screen for switching the unit On/Off   |

# 3 pLAN management between boards

The pLAN network identifies a physical connection between the cards (pC01 pC0<sup>2</sup>, pC0<sup>3</sup>) and the external terminals.

pLAN=p.C0 L.ocal A.rea N.etwork.. The purpose of the pLAN network connection between the cards is to exchange variables among the cards with a logic decided by the program, in order to make the cards work together functionally.

The variables exchanged among the cards have already been established by the program, and likewise their direction of origin and destination. Therefore, the user does not have to set them, but has only make the electrical connections.

The following is a layout of the pLAN network

The main MO mask shows the address of the connected card in the bottom left-hand corner. With the terminal showing 32, it is possible to view all the boards without the need for other terminals.

# 3.1 How to assign the pLAN addresses

The pLAN addresses have to be unequivocal and correspond with the diagram shown above. There are various means of assigning the pLAN address

## 3.1.1 PGD0 Terminal

To direct (default level is 32) a PGD0 terminal, one has to:

- 1. Provide the terminal with voltage
- 2. Press the Up + Down + ENTER buttons until a "display address setting" appears
- 3. Type in the numerical pLAN address with the Up and Down buttons, then confirm by pressing Enter
- 4. The "No link" screen appears
- 5. If the "NO Link" screen does not appear, press Up + Down + ENTER again
- 6. Once the "display address setting" screen appears, press Enter 3 times

Once the "adr Priv/shard" screen appears, set the correct levels and confirm by typing in "YES"

# 3.1.2 pCO1- pCO3 addressing

Here is a description of the operations necessary for addressing pLAN from the pCO<sup>1</sup>, pCO<sup>3</sup> cards.

- 1. Power down the pC0<sup>1</sup> card and connect a LCD 4x20 / PGD0 terminal with the pLAN "0" address.
- 2. Power up the pC01 card, by holding down the Alarm + Up keys until a mask appears
- 3. When the "pLAN Address" screen is shown, perform the indicated operations, i.e. insert the numeric (1,2,.3 or 4...) pLAn address with the Up and Down keys and then confirm by pressing Enter.
- 4. Power down the pCO\* card.
- 5. If necessary, assign the correct pLAN address to the external terminal if specified.
- 6. Power up the pCO\* card.

# 3.1.3 pCO2 addressing, PCOI/PCOT terminals and EVD-200 valve driver

The pLAN addresses on these are set with binary logic, changing the position of a group of dip-switches located at the back of the pCOI / PCOT terminals, on the pCO2 cards and inside the EVD-200 electronic valve drivers, with all the devices compulsorily powered down. For further information, consult the specific manual for the device.

In all the other screens in the program, to display the address of the board that is currently connected, press the printer button or Enter+Prg, depending on the terminal used.

# 4 Installation of default values

When you have checked the connections between the cards and terminals, power up the pC0 card/s\*.

When the machine is powered up, the software automatically installs the default values selected by CAREL for all the chiller and driver configuration parameters. This section tells you how to reset default values to return to the initial conditions. Therefore, this operation need not be carried out at the first power-up. The following procedure is used for resetting all the in-plant configuration parameters selected by CAREL:

#### ATTENTION! this procedure irreversibly cancels any programming done by the user

As resetting the default values is an operation that concerns each pCO\* card, if there are two or more cards, repeat the operation for each card. The procedure is <u>identical</u> for all the cards.

These are the steps:

- press the "menu" and "prog" keys simultaneously on the terminal with 15 keys (PRG in the terminals with 6 keys). Once they have been pressed, both the LED above the "menu" key and the one above the "prog" key should light up (lighting up of LEDs on the PRG key in the terminals with 6 keys).
- Input the password using the "arrow" keys and press Enter: in this way, you enter the "constructor" configuration :

```
Manufacturer |
|Type in password |
| 0000
```

• press the up arrow key to rapidly reach the default values installation screen:

```
+-----+
|Erase memory V0|
|Install global |
|default values S|
|Please wait... |
+----+
```

• press the "enter" key to position the cursor above the letter "N", and take it to "S" with the arrow keys. The "please wait..." words appear immediately. The following screen will appear after a few seconds:

| ++                  |                      |  |  |  |
|---------------------|----------------------|--|--|--|
| DEFAULT STATUS:     |                      |  |  |  |
| 1:  2:? 3:? 4:-     | Default complete     |  |  |  |
| > Switch-off unit < | ? Default in process |  |  |  |
| > to data confirm < | - No unit            |  |  |  |
| ++                  |                      |  |  |  |

1

• wait for the defaults to have been installed in all the units, then restart the units.

# 5 Language option

When the unit is powered up, a screen appears by default, where you can select the language to be used (Italian/English/French/German/Spanish). This mask stays active for 30 seconds. When this time has elapsed, the program automatically changes over to the main menu (M0 screen) This function can be disabled. How to disable it:

- 1. Press the PROG (PRG) button and access PO screen
- 2. Enter the correct password.
- 3. Go to screen "Pc", pressing the down arrow repeatedly
- 4. Select "N" under item "Show language screen at start-up".

In any case, you can change the language in use at any time. To do this, all it takes is to go to the third screen (Ak) in the maintenance menu.

# 6 Selecting the unit of measure

The unit can be configured for operation with different units of measure for the temperature and pressure, depending on the target market. The options are metric (°C / Bar) or imperial (°F / Psi ).

To change the setting, proceed as follows:

- 1. Press the PROG (PRG) button and access PO screen
- 2. enter the correct password;
- 3. go to screen "Pm", pressing the "down arrow" repeatedly;
- 4. choose "METRIC" or "IMPERIAL" for the item "Type of unit of measure".

After the selection has been made, all the parameters are converted into the new unit of measure.

#### 7 List of inputs/outputs

Inputs and outputs are listed below based on unit type. A number has been associated with each type of machine. This number is the program's main parameter because it identifies the inputs and outputs configuration. Using this list of inputs and outputs, select the number you require from the numbers associated in the program configuration screens.

# AIR/WATER UNIT WITH MAX. 4 SCREW COMPRESSORS (UP TO 4 CAPACITY STAGES PER COMPRESSOR)

#### **CHILLER-ONLY UNIT - MACHINE TYPE "0"** 7.1

# 8 List of parameters

The table below describes program parameters along with the following additional information: screen code (screens have a code in the top right corner) to make identifying the parameter easier (screen), factory setting, upper and lower limits of the range within which values can be effected, unit of measurement, and an empty column for writing the desired value.

- To find the parameter you are interested in on the terminal's display, proceed as follows:
  - Locate the parameter in the table below and the code of the screen it appears on
  - Using the list of screens (coming section) and screen code, call up the screen on the terminal

| DESCRIPTION OF PARAMETER   | SCREEN             | SLAVE           | FACTORY VALUE   | VALUE           | RANGE                          | UNIT<br>MEASUREM<br>ENT |

# 9 Screens

#### Screens can be divided into 5 categories:

USER screens, not password protected: they appear in all loops except "prog" and "menu + prog" and show probe values, alarms, hours of operation of the devices, time and date, and can be used to set temperature and humidity setpoints and for clock set-up. They are marked with the " $\mathbf{O}$ " symbol in the parameters table below.

password-protected USER screens (password 1234, editable): called up by pressing the "prog" key, via these screens you can set the main functions (times, setpoints, differentials) of connected devices. Screens referring to functions that are not available are not displayed. They are marked with the "O" symbol in the parameters table below.

password-protected MAINTENANCE screens (password 1234, editable): called up by pressing the "maintenance" key. Via these screens you can monitor devices, set connected probes, edit hours of operation and manage devices in manual mode. They are marked with the "@" symbol in the parameters table below.

password-protected MANUFACTURER screens (password 1234, editable): called up by pressing key combination "menu + prog" - via these screens you can configure the air-conditioner and enable main functions, as well as choosing connected devices. They are marked with the "O" symbol in the parameters table below.

# 9.1 List of screens

Following is the list of screens shown on the display. The table's columns represent screen loops, and the first screen (A0, B0...) is the one that appears when you press the relevant key. You can then use the arrow keys to scroll through the others. The codes (Ax, Bx, Cx...) appear in the top right comer of the screens, making them easier to distinguish. The meaning of the symbols  $\mathbf{O}, \mathbf{O}...$  is explained in the previous paragraph. The PSW symbol indicates screens where you are required to enter passwords.

# 10 EVD 200 electronic expansion valve

The EV Driver module for piloting the electronic expansion valves (EEV) for the pLAN network, makes it possible to control intake superheating to enable the refrigerating unit to operate more efficiently and with greater versatility.

We say efficiently, because by improving and stabilising the flow of refrigerant to the evaporator, we increases the system's overall performance, while guaranteeing safety (low pressure pressure switch less frequently tripped, fewer returns of liquid refrigerant to the compressor,...). Furthermore, if the EEV is correctly sized, use of condensation pressure (or evaporation pressure,) either floating or at low set point, considerably increases the system's efficiency, while ensuring lower energy consumption and greater refrigerating yield. It is versatile, because the electronic expansion valve makes it possible to serve refrigerating units with a lower refrigerating capacity and in operating conditions which may differ considerably from each other.

Using an expansion valve entails the installation not only of the EVDriver and the expansion valve itself, but also of a temperature sensor and a pressure transducer, both located on the refrigerating side at the end of the evaporator (on the compressor's intake pipe). Consult the following diagram for a better understanding of the system's typical lay-out. The priorities to be considered for optimal control of the refrigerating system: obtaining a

## Evaporator

high, constant refrigerating yield rather than very low, stable superheating. The heart of the control is a PID control with settable coefficients for superheating. These are the additional controls:

- LOW (Low superheating with integral time and adjustable threshold)
- LOP (Low evaporation pressure, operating in transients only, with integral time and adjustable threshold)
- MOP (High evaporation pressure with integral time and adjustable threshold)

HiT cond (High condensing pressure, activated with condensing pressure probe read by the pCO, with programmable integral time and threshold)

# 10.1 Driver parameters

Below are shown the fundamental and most important parameters to operate the EVD200 driver.

The parameters are divided into three different branches that can be accessed via the EVD menu:

- System parameters (information on what is physically installed)
- Autosetup (Standard information on the kind of unit)
- Advanced parameters (parameters who should be changed by experts)

IMPORTANT : in order for the unit to operate, the parameters in the "system parameter" and "autosetup" branches should be inserted. Otherwise, an alarm will appear to indicate that the autosetup procedure has not occurred.

#### 10.1.1 BRANCH system parameter

#### Battery presence

Indicate the presence of the battery connected to EVD

#### Valve type

Insert the kind of electronic valve used, a read only parameter will indicate the number of maximum regulation passes of the valve (useful for identifying certain valve models should the trade name be changed))

Alco EX5 Alco EX6 Alco EX7 Alco EX7 Alco EX8 SPORLAND 0.5-20tons SPORLAND 25-20tons SPORLAND 50-250tons CAREL E2V\*\*P CAREL E2V\*\*P CAREL E2V DANFOSS ETS-25/50 DANFOSS ETS-25/50 DANFOSS ETS-25/400 CUSTOM An incorrect choice of valve or configuration of the CUSTOM valve can damage the hardware of the valve itself.

#### Refrigerant

Select the kind of refrigerant used.

R22, R134A, R404A, R407C, R410A, R507C, R290, R600, R600A, R717, R744, R728, R1270.

#### CUSTOM VALVE CONFIGURATION

If a CUSTOM valve is selected, the configuration levels shown below appear.

#### Minimum Steps

Minimum opening steps used only in repositioning to capacity change.

#### Maximum Steps

Maximum opening steps

#### **Closure Steps**

Steps to obtain a complete closure of the valve

# Extra Opening Step

Enabling opening steps beyond the maximum ones.

Do not activate if one's own expansion valve has an overall course (closure steps) greater than the controlling course (Maximum steps) for example with the Sporlan valve.

Do not use without prior authorisation from one's own EEV supplier at the enabling of the steps against the opening mechanical end stroke. These steps are given every second up to 30% of the maximum steps in the event that the valve is completely open with overheating above the setpoint. On return to normality (superheat below the setpoint and/or valve opening below maximum) the meter for the extra steps provides is reset and if the fault reappears, others will be provided again 30% greater than the maximum steps.

#### Extra Step Closure

Enabling of closure steps with valve already completely closed.

Do not use without prior authorisation from one's own EEV supplier at the enabling of the steps against the closure mechanical end stroke.

These steps are given every second up to 30% of the maximum steps in the event that the valve is completely closed with overheating below the setpoint. On return to normality (superheat above the setpoint and/or valve opening different from zero) the meter for the extra steps provides is reset and if the fault reappears, others will be provided again 30% greater than the maximum steps.

Movement Current Stationary Current Step Frequency Duty Cycle Report on maximum gear.

Indicate the maximum time percentage (based on a second) where the valve can be running (to avoid superheat of some motors).

#### EEV steps in standby

Represents the number of steps that the valve maintains during the adjustment pauses (unit at OFF).

By selecting a level greater than zero, the valve will remain partially open.

If a solenoid value is installed before the expansion value, this level can be increased (e.g. 25% of the maximum steps) to minimise the risks of blocking the value (due to ice, dirt, wear...)

# Pressure sensor limits (deafault -1..9.3 barg)

Range of an adjustment sensor for overheating connected to the EVD.

#### ALARMS DELAY

Low Superheat (Default 120 S) A zero level deactivates the alarm. High Superheat (Default 20 Min) A zero level deactivates the alarm. LOP (default 120 s) Delay alarm for evaporation low pressure. A zero level deactivates the alarm. MOP (default 0 s)

Delay alarm for evaporation high pressure. A zero level deactivates the alarm.

#### 10.1.2 BRANCH autosetup

#### Start up opening percentage

Insert the ratio between the circuit potential and that of the valve, considering the circuit at 100%. The percentage is always lower than or equal to 100% the valve will always be larger than the circuit where it is installed. This percentage is used to calculate the position of the first opening (pre-positioned) of the valve when the circuit starts up. In the case of non modulating circuits (0% or 100%), the percentage is the only parameter that influences the first opening: by selecting 40% the valve will open 40% of its controlling course. In the case of *stepped circuits* (e.g. 0%-25%-50%-100%), the valve will open 40% of the controlling course multiplied for the first step of the circuit (e.g. 40%\*25%=10%).

The parameter is changed according to the ideal obtained from the ratio of the circuit/valve capacity so that when the circuit is turned on, there is no considerable liquid reflux (for more than a minute, in this case reduce the percentage) or excessively low evaporation pressure problems for an excessively long period (in this case increase the percentage). The parameter also automatically influences certain PID regulation levels (proportional gain).

#### Kind if compressor or unit

Insert the unit/compressor category in which the expansion valve is used.

This selection optimises the PID control parameters and the Driver's auxiliary protection, bearing in mind the control specifications in the various kinds of plant. The following choices are available:

Alternative Screws Scroll Rapid Group / Cell Group / Cell

#### Kind of load step

In this field, one must insert the kind of capacity control used in the circuit.

The following choices are available:

None or steps: compressor without load steps or with step load steps.

Slow continuation: compressor with continuous modulation that is not particularly fast or with a considerable inertia speed (e.g. case for screw compressors) compressor with fast continuous modulation or with low inertia (e.g. control with inverter or with speed case)

#### Kind of evaporator

Insert the kind of exchanger used as evaporator for the hot and/or cold modes: depending on the reversibility of the circuit there can be either one or two fields. The following choices are available:

Metal sheets Plates/pipes Fast Finned Slow Finned

#### Minimum saturation temperature ( LOP )

Separately set the limits lower than the evaporation temperature for the operational modes available (Cold, Hot, Defrost). The level to be inserted is not the calibration level of a low pressure switch but the minimum temperature of acceptable evaporation for the unit in continuous operation.

For example, for water refrigerator without glycol with water outlet setpoint at 7°C, a typical level is -2°C.

On the other hand, for a heat pump, the level could also be lower than -20°C depending on the use and project characteristics. In the case of centralised unit (e.g. supermarket) and/or multi-evaporator where the behaviour of the valve does not influence the evaporation pressure (being set a compressor pack) set at -50°C (function not operational).

#### Maximum saturation temperature ( MOP )

Separately set the limits greater than the evaporation temperature for the operational modes available (Cold, Hot, Defrost). Once this threshold has been reached, the expansion valve will start to modulate (closing) in order to stay below. Obviously in these cases, the superheat control will be abandoned: the MOP work point normally helps maintain the superheat considerably above the set setpoint.

#### • Superheat high alarm threshold Default 20°C

Insert the maximum superheat for the generation of the relative alarm (delay set in the system branch). This parameter shows a double field like the one in the advanced branch.

## 10.1.3 Advanced BRANCH

This branch allows for the configuration of all the expansion valve control parameters that is generally unnecessary.

For each parameter, in this section, two fields are shown. The left hand field shows the level set by the AUTOSETUP procedure and cannot be changed since it is read only. The right hand field can be changed (by default equal to zero that means the use of the autosetup parameter) and makes it possible to change the level of variation used by the control. The description of the parameter can start with a prefix indicating on which operational mode it will be used: CH: COLD mode

HP: HOT mode

DF: DEFROST mode

#### • EEV opening percentage

Percentage of initial opening of the valve on activation of the driver/circuit.

#### • Set superheat

Superheat target level that the driver aims at. Do not set levels that are too low (less than  $5^{\circ}$ C) or too close to the limit of low superheat (a difference of at least  $3^{\circ}$ C).

#### Proportional gain

Proportional gain of the PID control.

On increasing this parameter, the valve's reaction speed increases, above all with frequent variations of superheat (e.g. fast capacity ramp or evaporator loading). This parameter influences all the valve's movements, not only those linked to the standard PID but also to the control of accessories (low superheat, high or low evaporation pressure.....)

#### Integral time

Integral time of PID control.

On the decreasing of this valve, the driver increases the number of steps sends a command to the valve every second to achieve the setpoint. High levels, therefore, reduce the integral action and slow down the valve movement.

Excessively low levels (below 20s) can create hunting to the system for excessive movements of the expansion valve. The level 0 (zero) completely cancels the integral action.

#### Low superheat

Limits of low superheat.

Below this level of superheat, the driver sends a command to the expansion valve for a faster closure speed than normal, in order to avoid liquid reflux. In fact, it represents an additional integral term to the PID control that intervenes below the threshold selected.

Do not set levels that are too close to the superheat setpoint (a difference of at least 3°C) or levels too close to zero (less than 2°C) in order to avoid the protection intervening in the event of an incorrect reading of the control probes.

#### Superheat neutral area

Neutral area for PID control. In this setpoint context, the driver will stop the control and the valve not make any movements. The control starts again when the superheat exits the neutral area.

#### Derivative time

Derivative time of PID control. Avoid levels greater than 4 seconds in order to prevent unstable control.

#### Low superheat integral time

Integral time for low superheat control.

On this parameter decreasing, the control of low superheat diverts more speed/energy. Levels close to 1.0 seconds are advised for fast evaporators (plates, piping bands....) and close to 10.0 seconds for slow batteries (refrigeration counters, centralised units..). A level of 0 (zero) disables the control.

#### LOP integral time

Integral control time at the protection stage for low pressure/evaporation temperature (LOP).

When this parameter diminishes, the control becomes faster.

Levels close to 1.0 seconds are advised for fast evaporators (plates, piping bands....) and close to 10.0 seconds for slow batteries (refrigeration counters, units..). It is advisable to deactivate for centralised use (supermarket use, centralised units....) A level of 0 (zero) disables the protection.

#### MOP integral time

Integral control time at the protection stage for high pressure/evaporation temperature (MOP). When this parameter diminishes, the control becomes faster.

Levels close to 2.5 seconds are advised for fast evaporators (plates, piping bands....) and close to 25.0 seconds for slow batteries (refrigeration counters, units..). A level of 0 (zero) disables the control.

#### Delay in MOP start up

The MOP action is disabled for this time when control starts.

This time is needed to allow for the achievement of low evaporation pressures in circuits that start with equalised pressures. in the case of excessively reduced times, the MOP control leaving the unit could be activated only because the evaporation pressure did not have the time to reach the "real" working level.

# High condensation temperature protection

#### Maximum condensation temperature.

Only use if the driver controls the condensation probe or receives the level from the main control (pC0...)

Over and above this level, the driver ignores the superheat control and progressively closes the expansion valve to limit the fridge capacity and subsequently the condensation pressure. This way, the evaporation pressure is considerably reduced. Only use in plants that can operate at negative evaporation temperatures and that do not have other methods to reduce the condensation pressure (unloading, capacity reduction....)

#### Integral time for high condensation temperature

Integral control time during the protection stage for high condensation pressure (HiTcond). When this parameter diminishes, the control becomes faster. Levels close to 5.0 seconds are advised. A level of 0 (zero) disables the control.

#### Dynamic proportional control

This function allows the driver to change the proportional PID gain depending on the actual circuit capacity.

In the case of valves that are particularly large and/or circuits with the possibility of working at low load steps (below 50%), this function allows for the automatic reduction of the gain in proportion to the low potential.

Use in the case of low potential, the valve seems to react too quickly/violently, causing hunting in the evaporation pressure and/or superheat. This is a particular function to activate, so it will only show one field.

#### 10.2 Special "go ahead" function

| Driver 1 status    |
|--------------------|
| Valve open restart |
| Go ahead? N<br>+   |

There are three alarm conditions which prevent the driver from performing normal control (one of these is shown above):

- an open valve  $\rightarrow$  during the last blackout, the valve was not shut completely
- battery charge
- $\rightarrow$  the battery is not operating correctly or it is discharged or disconnected eeprom restart  $\rightarrow$  malfunctioning eeprom

When one of these conditions is active, the following alarm appears:

```
AL086
Driver1:Waiting for
eeprom/batt.charged
or open valve error
```

With the "Ignore" function, these alarms can be ignored to enable the driver to control the valve (otherwise the driver would keep the valve shut).

WARNING! deleting the alarms means ignoring them, and consequently it is recommended to carefully check that the system is not damaged or malfunctioning or becomes unreliable (e.g.: if "recharge battery" is signalled, it probably means that the battery is not charged or is not connected, etc. Consequently, in the event of a blackout, it may not be able to close the valve. The valve would thus remain open when the installation starts again). If none of the three above alarms is present, the screen changes over to the next screen:

| +-  |     |      |   |     |     | -+ |
|-----|-----|------|---|-----|-----|----|
| ł   | Dri | ver  | 1 | sta | tus | 1  |
| ł   |     |      |   |     |     |    |
|     | No  | faul | t |     |     |    |
| ł   |     |      |   |     |     |    |
| + - |     |      |   |     |     | -+ |

# 11 Unit On/Off

There two power-up and power-down modes for the machine:

- 1. Power-up and power-down of System
- 2. Power-up and power-down of Circuit

The unit status can be controlled from the keypad, digital input (can be enabled), supervisor (can be enabled)

The power-up/power down operation with the ON/OFF key on the keyboard has absolute priority. When this key is pressed, the green LED (ON or OFF) near the key will indicate the current status.

The machine can be powered up or down from the supervisor and/or the digital input, only if it was powered up from the keyboard. Any power-down from the supervisor or digital input will be signalled by the flashing of the green LED on the ON/OFF key and by a special wording on the main menu screen.

#### Power-up and power-down of System

Control is by the master board : if the board is powered up, it will power up also all the system's slaves, and vice-versa if OFF.

#### Power-up and power-down of Circuit

Control is by the slave board : the individual slave boards can be powered up or down from the supervisor/digital input, only if the master card is ON.

The main mask of the terminal connected to master board shows, on normal working, the status of unit. If the master circuit is switch-off, by digital input, the status blink between unit status and circuit off (Circ.OFF).

# 12 Control

There are two different modes for controlling the control thermostat:

- control depending on the water temperature values measured by the probe installed at the evaporator inlet;
- control depending on the water temperature values measured by the probe installed at the evaporator outlet.

In the first case, the control is proportional and based on the absolute temperature value measured by the probe; in the second case, control features a dead band based on the time the temperature measured by the probe remains over certain thresholds. The type of control in any case depends on the type of compressor managed:

- if the compressor features stepped capacity control (load steps) then either type of control can be used;
- if the compressor features continuous capacity control, then only outlet temperature control will be available.

# 12.1 Control set-point

#### Employed Inputs:

- Digital input to enable second set point
- Analogue input for remote set point variation
- Supervisor serial network
- Employed Parameters:
- Control set point
- Enable second set point from digital input
- Enable remote set point from analogue input
- Limits for calculating remote set point from analogue input
- Display set point used by the control

#### Description of operation

The temperature control, irrespective of the type, is based on the setting of two fundamental parameters: set point and control band. The control set point can be changed according to the operating requirements of the unit.

There are four different ways to change the control set point:

- Different from the screen: accessing the special screen, the user can set the value of the parameter directly.
- <u>Different from the supervisor</u>: if a supervisory system is connected, the cooling or heating set point can be modified by accessing the dedicated addresses.
- <u>Different from digital input</u>: enabling the management of the secondary set point, the set point defined on the dedicated screen will be replaced by the corresponding user parameter, depending on the status of the digital input.
- <u>Different from analogue input</u>: enabling the remote set point from analogue input (0-1V) will activate the control set point compensation, with a proportional value between the two limits for the conversion of the input signal.

All the conditions may exist together, condition "1" is always active, while the others can be enabled or disabled separately.

# **12.2** Inlet temperature control

- Employed Inputs:
- Water temperature at evaporator inlet
- Employed Parameters:
- Type of unit
- Total number of compressors
- Type of compressor capacity control
- Number of Capacity Control Steps
- Control set-point
- Proportional band for control at inlet.
- Type of control (proportional or proportional + integral)
- Integration time (if the proportional + integral control is enabled)
- Time between start-up and first capacity control
- Time between first and second capacity control
- Time between second and third capacity control
- Time between third and fourth capacity control

Outputs used:

- Liquid Solenoid
- Windings for compressor Line Delta Star
- All compressor capacity control relays

The thermostatic control according to the values measured by the temperature probe at evaporator inlet, is based on proportional control. According to the total number of configured compressors and capacity control steps per compressor, the set control band will be subdivided into a certain number of steps of equal amplitude. When the activation thresholds of the individual steps is exceeded, a different compressor or capacity control steps will be activated. To determine the different activation thresholds, the following relations must be applied:

- Total number of control steps : Total number of compressors \* Number of capacity control/compressor steps
- Step proportional amplitude = Proportional control band / Total number of control steps
- Step activation thresholds = Control set-point + (Step proportional amplitude \* Step sequential number [1,2,3...]

# 12.3 Outlet temperature control

Employed Inputs:

Water temperature at evaporator outlet

Employed Parameters:

- Type of unit
- Total number of compressors
- Type of compressor capacity control
- Number of capacity control steps
- Control set-point
- Control band for outlet control
- Delayed starting of compressor capacity control stages
- Devices activation delay
- Devices disablement delay
- Summer limit of temperature at outlet (powers down all compressors without observing the disabling time)
- Winter limit of temperature at outlet (powers down all compressors without observing the disabling time)

Outputs used :

- Liquid Solenoid
- Windings for compressor Line Delta Star
- All compressor capacity control relays

# Richiesta di disinserimento

A neutral temperature zone is identified, based on the set set-point and band values.

- Temperature values between the set point and set point + band (A < Temperature < B) will not switch any compressors On/Off.

- Temperature values above set point + band (Temperature > Point B) will activate the compressors

- Temperature values below the set point (Temperature < Point A ) will deactivate the compressors

A temperature threshold, subdivided into summer and winter operation is also specified: the installed devices are unconditionally disabled above/below this threshold, in order to prevent the units producing too much cold/heat.

Richiesta di inserimento

With capacity-control compressors, the activation and deactivation occur further outside of point A and B. See the chapter Continuous capacity control with outlet control.

# 12.4 Control of water /water chiller only units

Employed Inputs:

- Water temperature at evaporator inlet
- Water temperature at evaporator outlet
- Water temperature at condenser inlet
- Water temperature at condenser outlet
- Employed Parameters:
- Type of unit
- Total number of compressors
- Type of compressor capacity control
- Number of capacity control steps
- Control set-point
- Control band
- Type of control (inlet outlet)
- Type of control at inlet (proportional proportional + integral)
- Integration time (if the proportional + integral control is enabled)
- Delayed starting of compressor capacity control stages
- Devices activation delay

Outputs used :

- Liquid Solenoid
- Windings for compressor Line Delta Star
- All compressor capacity control relays

#### Description of operation:

Activation of compressors is controlled by the water temperature measured by the probe located at evaporator inlet/outlet. No condensation fans are supplied because the condenser is water-cooled.

# 12.5 Control of water/water chiller unit with gas reversing heat pump

Employed Inputs:

- Water temperature at evaporator inlet
- Water temperature at evaporator outlet
- Water temperature at condenser inlet
- Water temperature at condenser outlet
- Employed Parameters:
- Type of unit
- Total number of compressors
- Type of compressor capacity control
- Number of capacity control steps
- Control set-point
- Control band
- Type of control (inlet outlet)
- Type of control at inlet (proportional proportional + integral)
- Integration time (if the proportional + integral control is enabled)
- Delayed starting of compressor capacity control stages
- Devices activation delay
- Refrigerating circuit reversing valve logic
- Outputs used
- Liquid Solenoid
- Windings for compressor Line Delta Star
- All compressor capacity control relays
- Refrigerating circuit reversing valve

# Description of operation:

Activation of compressors is controlled by the water temperature measured by the probe located at evaporator inlet/outlet. No condensation fans are supplied because the condenser is water-cooled.

During the reversing of the refrigerator cycle, i.e. at changeover from refrigeration to heating and vice-versa, the evaporator and condenser functions are exchanged. In this mode, the refrigerating circuit is reversed, but the compressors are always controlled by the temperature at evaporator inlet/outlet.

# 12.6 Control of water/water chiller unit with water reversing heat pump

# Employed Inputs:

- Water temperature at evaporator inlet
- Water temperature at evaporator outlet
- Water temperature at condenser inlet
- Water temperature at condenser outlet

Employed Parameters:

- Type of unit
- Total number of compressors
- Type of compressor capacity control
- Number of capacity control steps
- Control set-point
- Control band
- Type of control (inlet outlet)
- Type of control at inlet (proportional proportional + integral)
- Integration time (if the proportional + integral control is enabled)
- Delayed starting of compressor capacity control stages
- Devices activation delay
- Water circuit reversing valve logic

Outputs used

- Liquid Solenoid
- Windings for compressor Line Delta Star
- All compressor capacity control relays
- Water circuit reversing valve

#### Description of operation:

Activation of compressors is controlled by the water temperature measured by the probe located at evaporator inlet/outlet. There are no condensation fans because the condenser is cooled using water. During the reversal of the refrigerator cycle, that is, during the passage from refrigeration to heating or vice versa, there is no exchange between the evaporator and condenser functions. In this mode, the water circuit is reversed, and the compressors are controlled by the temperature at evaporator or condenser inlet/outlet according to the selected mode.

# **13** Types of controlled compressors

# 13.1 Stepped capacity control

A maximum number of four compressors are managed, with a maximum of four capacity control steps each. Capacity control is achieved by three relay outputs which, when suitably commanded, short-circuit the refrigerant thrust by the compressor, varying its capacity and, therefore, the power input into the circuit.

#### Configuration of stepped capacity control relays

The enabling sequence of the capacity control relays differs for each compressor. Therefore, the software has a facility for configuring the enabling sequence according to the needs of different compressor manufacturers. For multi-card systems: as several compressors are housed on the same machine, it is considered that the compressors controlled by each pCO are perfectly equal and, therefore, the capacity control configuration selected on board the master card also applies to the slave cards. The following table shows examples of the configuration of the dedicated digital outputs for the different power stages entered. The effective status of the digital output is indicated. The relation between the data in the table and the values set on the display. Closed = ON Open = OFF

#### Default configuration :

| % LOAD | Relay 1 | Relay 2 | Relay 3 |
|--------|---------|---------|---------|
| 25%    | CLOSED  | OPEN    | OPEN    |
| 50%    | OPEN    | OPEN    | CLOSED  |
| 75%    | OPEN    | CLOSED  | OPEN    |
| 100%   | OPEN    | OPEN    | OPEN    |

Configuration example :

| % LOAD | Relay 1 | Relay 2 | Relay 3 |
|--------|---------|---------|---------|
| 25%    | OPEN    | CLOSED  | CLOSED  |
| 50%    | CLOSED  | CLOSED  | OPEN    |
| 75%    | CLOSED  | OPEN    | CLOSED  |
| 100%   | CLOSED  | CLOSED  | CLOSED  |

#### Stepped capacity control times

Delays are specified for capacity control management. These delays can be set when the capacity controls are enabled. Such delays indicate the minimum operating time of a compressor at a given power stage. If the machine is enabled at maximum level request, these delays prevent a changeover from power level 0 to maximum level.

Graph of times for capacity control in 4 steps:

With Bitzer compressor the time T2-T3-T4 are force the follow value:

T2: The minimum value is force to 10 second

T3: zero

T4: zero

The T1 time does not have restriction.

To have more flexible management of the unloader during the unit start up and the normal working condition, it is possible to set a time (mask Te) starting from the pump on and after this the unit is in normal working mode. If this time equal to zero then the management is disable. During start up mode the time T1, T2, T3 (mask T7) are respected, but in normal mode they are ignored and an equal time for all the uloaders is used set by mask Te. With Bitzer compressor the minimum time is force to 10 second.

#### Special management of capacity control first stage

A facility is provided for enabling special management of the first stage of capacity control, managing the compressor's special requirements when it is operating at low power. In general, the control entails the use of the first capacity control stage only at power-up and if temperature falls below the control set-point. When controlling the compressor, this type of control uses a reduced power modulation range, between the second and maximum power stages.

Management varies according to whether the compressor is in its starting or disabling stage. In both cases, you are recommended not work at 25% power for too long.

- <u>Starting</u>: after being started, if the compressor does not receive any thermostatic request for changeover to the second capacity control stage, the changeover is forced by the software after a time which can be set on the screen (T1).
- <u>Power-down</u>: if a reduction in the power of the circuit is requested, power is controlled between the maximum and second capacity control stage. Only if
  temperature drops below set-point value, the compressor is forced to operate according to the first capacity control stage for the set time (T1).

This special operating mode is enabled from the screen. If the first capacity control step is not enabled, it is treated as just any step. The compressor can operate at this power level for an infinite time.

# 13.2 Stepped capacity control with control at inlet

A description of stepped capacity control of 4 compressors with four capacity control steps each:

All compressors and the relevant capacity control steps will be proportionally positioned in the band. Increasing temperature values will cause the control steps to be subsequently input. Each step will be input according to the set delay times. The compressors will be started at the first entered capacity control stage. If special management of the first capacity control stage was selected, control will be effected according to the description in the dedicated section. In any event, the times for the capacity controls will be applied as described.

# 13.3 Stepped capacity control with control at outlet

A description of stepped capacity control of 4 compressors with four capacity control steps each:

#### Activation of compressors

if the water temperature measured by the probe located at the evaporator outlet exceeds the threshold of Control Set-point + Control Band (Point B), the number of power stages will be increased - the power stages were input according to the set parameter known as "request time between steps switch-on" (mask Po).

In this configuration the time between the activation of the steps will be equal to the set time between the starts of different compressors, while in the event of capacity-control, the delay time between load steps set will still be applied, and therefore the higher of the two times will prevail.

#### Power-down of compressors

If the water temperature measured by the probe located at the evaporator outlet falls below the Control set point (Point A), then the number of load steps will be decreased, according to the parameter" request time between steps switch-off" (mask Po).".

If the temperature falls below the forced off threshold, the compressors are stopped irrespective of the set delays, to avoid the activation of the antifreeze alarm.

# 13.4 Continuous capacity control

A maximum number of four compressors are managed, with continuous capacity control. The compressor's capacity is controlled by two relay outputs, which, when suitably controlled, enable compressor power to be increased or reduced, varying the capacity of the compression chamber. Compressor power is controlled by sending impulses to the outputs of the capacity control relays. These impulses command the compressor to be charged or discharged. These impulses are at a constant frequency, settable, and of variable duration between two minimum and maximum limits, also settable. As there is no acquisition regarding the absolute position of the compressor 's capacity control valve, and, consequently, as no direct verification is possible of the power percentage input in the circuit, a time based control is run. With this control, when a set time threshold is reached, the compressor is considered fully charged/discharged and thus control of the capacity control impulses is suspended.

#### 13.4.1 Configuration of continuous capacity control relays

The control method of the capacity control relays differs for each compressor. Therefore, the software has a facility for configuring the enabling sequence according to the needs of different compressor manufacturers.

For multi-card systems: as several compressors are housed on the same machine, it is considered that the compressors controlled by each pCO are perfectly equal and, therefore, the capacity control configuration selected on board the master card also applies to the slave cards. The following table shows examples of the configuration of the dedicated digital outputs for the different power stages entered.

The effective status of the digital output is indicated.

The relation between the data in the table and the values set on the display.

Closed = ON

Open = OFF

## Default configuration :

| Compressor behaviour | Relay 1 | Relay 2 |
|----------------------|---------|---------|
| Power reduction      | CLOSED  | CLOSED  |
| Power stand-by       | OPEN    | CLOSED  |
| Power increase       | OPEN    | OPEN    |

The power stand-by configuration is taken on by the outputs when no variation of input power is requested, or if the maximum/minimum compressor power is reached, or because the water temperature measured by the probe located at evaporator outlet is inside the neutral control zone. For compressor charging /discharging, the digital outputs of the pCO card are commanded alternately according to the stand-by and charge/discharge configuration, causing the dedicated relay to pulse.

# 13.5 Continuous capacity control with control at outlet

Temperature control with compressors on continuous capacity control can occur only if control at outlet is selected, according to the temperature values measured by the probe located at evaporator outlet. To that end, further configuration parameters are input. They are specific for the particular type of compressor, and are added to those previously mentioned in the description of the special type of control.

Employed Parameters:

- Neutral zone for continuous capacity control
- Impulse period
- Charging impulse minimum duration
- Charging impulse maximum duration
- Discharging impulse minimum duration
- Discharging impulse maximum duration
- Forced discharge period at compressor power-up
- Capacity control relay forcing enabled when compressor is OFF:

Outputs used :

- Compressor capacity control Relay 1
- Compressor capacity control Relay 2

#### 13.5.1 Control of continuous capacity control according to points in the graph

According to the set-point values, the control band with control at output and the neutral zone of compressors on continuous capacity control, points C, D and E are identified. If the water temperature measured by the probe located at evaporator outlet exceeds point E

Point E = Control set point + Control band/2 + Dead zone /2

Then there will be a request for the compressor to start and an increase in capacity according to charge impulses of the maximum duration until reaching the maximum compressor load time. If the water temperature measured by the probe located at evaporator outlet is below point B Point B = Control set point + Dead zone /2 - Control band/2

In this case, there is a request for the compressors to be discharged according to the maximum duration impulses until compressor maximum discharging time is reached and until possible power-down. If the water temperature measured by the probe located at the evaporator outlet is between points D-E/B-C

Point D = Control set point + Dead zone

Point C = Control set point

Then the power of the compressor will be increased/reduced by impulses of variable duration according to the values calculated within the minimum and maximum limits set for an infinite time.

#### 13.5.2 Power-up of compressors (temperature above point E)

The compressors are powered up in sequence at a rate calculated by the set time required to reach maximum power. As there is no absolute measurement of the effective capacity, when the compressor is started it performs a forced unload cycle for a set time (unloader relays energised continuously according to the unload configuration). Subsequently, the compressor power will be increased by maximum duration impulses.

#### 13.5.3 Increase of compressor power

When the maximum time limit for reaching maximum power is reached, a forced charging cycle is commanded for a time of 20% of the set threshold, then the compressor capacity control relays change to the power stand-by configuration.

If the temperature remains in the power-up zone (beyond point E), every ten minutes a forced charging cycle is commanded with a duration of 20% of the time required to reach the maximum set power.

In the case of multi-compressor units, the periodic forced charging cycle will be carried out by all powered-up compressors which have reached maximum power.

#### 13.5.4 Modulated increase of power (temperature in range between points D-E)

The compressor's power is modulated in this temperature range, by applying charging impulses of variable duration to the capacity control relays (duration is calculated between the minimum and maximum values set according to the measured temperature values).

For multi-compressor units, modulated increase of power will occur simultaneously for all powered-up compressors.

#### 13.5.5 Operation of compressor in neutral zone (temperature in range between points C-D)

If the temperature value locates inside the neutral zone, the capacity control relays of all powered-up compressors change to the power stand-by configuration, thus maintaining the power level that had been reached.

#### 13.5.6 Modulated reduction of power (temperature in range between points C-B)

The compressor's power is modulated in this temperature range, by applying discharging impulses of variable duration to the capacity control relays (duration is calculated between the minimum and maximum values set according to the measured temperature values). For multi-compressor units, modulated reduction of power will occur simultaneously for all powered-up compressors.

#### 13.5.7 Power-down of compressors (temperature below point B)

The compressors are first unloaded by sending unload impulses of the maximum duration to the unloader relays. The compressors are then powered down, by reducing the number of requested devices, at a rate equal to the time required to reach minimum set power.

FIFO Rotation is applied, whereby the first powered-up compressor is discharged and then powered-down. Instead, if rotation is disabled, the last powered-up compressors is discharged and then powered down.

#### 13.5.8 Derivative regulation in the increasing zone

In the increasing zone, Tb mask, comes controlled every "Derivative Time" if the outlet temperature is changed in order more than 0,2 °C. If this is true the compressor remains in stand-by until the new control. This management can be disabled with "Derivative time" equal to 0.

# 14 Compressor rotation

Compressor calls are rotated in order to equal the number of duty hours and power-ups among the devices. Rotation follows the FIFO logic: the first compressor to be powered up is the first to be powered down. At the initial stage, there may be considerable differences in the on-duty hours of the compressors, however, the hours are very similar to each other in steady state. Rotation occurs only among compressors and not among capacity controls, and, in any case, this type of rotation operates only if the compressors have stepped capacity control.

- Rotation-free management
   Power-up: C1 C2 C3 C4
- Power-up: C1,C2,C3,C4.
   Power down: C4 C2 C2 C1
- Power-down: C4,C3,C2,C1.

FIFO rotation management (the first compressor to be powered up is the first to be powered down):

- Power-up: C1,C2,C3,C4.
- Power-down: C1,C2,C3,C4.

## 15 Starting a single compressor

#### 15.1.1 Description of operation

The start-up stages are described in the following graph

From mask T7 it is possible to set the liquid solenoid and compressor start sequenze. Pay attention that during this time the condenser fan are force to maximum speed.

## 15.2 Starting the compressor motor

#### 15.2.1 Delta / Star starting

Starting the motor is described in the following diagram

### 15.2.2 Start-up with Part - Winding

To start the compressor with part-winding, you must reset the star and delta-star times, setting the desired part-winding time as the delta-star time. The outputs used are those of the line and triangle relays, used respectively as part-winding relays A and B. Example: Star-line time 0 / 100 s Star Time 0 / 100 s

Delta-star time 100 / 100 s

for a part-winding time of 1 s.

## **15.3 Compressor start restrictions**

There are two start restricting methods. Both start the compressor directly with the delta contactor, by-passing the star contactor. There is a single enablement for both cases:

1. Set high and low pressure thresholds exceeded

2. Set equalised pressure threshold exceeded (equalised pressure is the average pressure between high and low pressure measured by the transducers).

# 16 Forced capacity control

## Inputs used

- Water temperature at evaporator outlet
- Compressor delivery temperature
- Condensation pressure
- Current

Parameters used

- High delivery temperature prevention threshold
- High delivery temperature prevention differential
- High pressure prevention threshold
- High pressure prevention differential
- Antifreeze temperature prevention threshold
- Antifreeze temperature prevention differential
- Forced selection of compressor at minimum/maximum power
- High current alarm threshold
- High current alarm percentage differential
- Delay time to signal the high current alarm
- Delay time to prevent high current from compressor start

Outputs used

All compressor capacity control relays

## 16.1 Description of the condensing pressure-antifreeze-discharge temperature prevent function

The compressor forced capacity control function prevents the unit from operating in abnormal conditions of pressure, refrigerated water temperature or condensation temperature, thus preventing any intervention by specific alarms. A parameter is provided for selecting the compressor operating mode if forced capacity control is enabled. The compressor can be taken to minimum/maximum power according to the selection when:

- High delivery temperature threshold exceeded
- High pressure threshold exceeded
- Antifreeze temperature threshold exceeded

#### 16.1.1 Description of the high current prevent function

If the probe for measuring the current input is enabled and correctly configured, forced capacity control is active for the high current condition.

The high current is controlled on a settable alarm threshold and differential. After a delay time from when compressor starts, is the current measured exceeds the set alarm threshold, a preventive action starts, which involves gradually decreasing the capacity of the compressor. The frequency of capacity reduction is equal to 1/3 of the set time T1 (delay time for signalling the high current alarm); in the case of compressors with stepped capacity control, the number of steps on will gradually be reduced, in the case of compressors with continuous capacity control, the unload will be managed with impulses lasting equal the minimum set time. There is a settable differential to return from the forced capacity control condition, expressed as a percentage of the alarm differential. The return of the current to values below the alarm threshold and in any case within the set differential will not cause any variation to the capacity of the compressor.

The activation of a further forced capacity-control function due to pressure or temperature will be managed by assigning higher priority to the function that involves a greater decrease in compressor capacity. The duration of the current measured above the alarm threshold for a continuous time that exceeds the set time, will involve the activation of the corresponding high current alarm, with the immediate shutdown of the compressor and the need for manual reset by the user.

### 16.1.2 Compressors with stepped capacity control

For compressors with stepped capacity control, forced capacity control means that the compressor has to operate at minimum or maximum power according to selection.

#### 16.1.3 Compressors with continuous capacity control.

For compressors with continuous capacity control, forced capacity control means that the compressor has to operate in continuous charging or discharging mode according to selection.

# 17 Solenoid-valve management.

#### Inputs used:

• Compressor delivery temperature

Parameters used:

- Solenoid-valve activation threshold
- Solenoid-valve differential

#### Outputs used:

• Economizer solenoid-valve, oil-cooler, liquid-injection

#### 17.1.1 Description of operation

A digital output is provided for controlling an economizer solenoid-valve, oil-cooler and liquid injection. Activation depends on the compressor discharge temperature read by the probe, as shown in the following graph:

## 18 Pump-down

#### Inputs used

• Low Pressure Pressure-switch Parameters used

## Enable pump – down

- Pump down maximum duration
- Outputs used

Liquid Solenoid

- Liquid Solenoid
- Windings for compressor Line Delta Star
- All compressor capacity control relays

### 18.1.1 Description of operation

If enabled, pump-down occurs by the thermostat disabling the compressor.

The duration of the function can be set, and ends after a maximum time or if the low pressure switch is activated. If any alarm powers down the machine or even just the compressor, the pump-down finishes immediately.

- The activation of the pump-down function operates the compressor in forced capacity control mode:
- for compressors with stepped capacity control, the compressor operates at the minimum/maximum capacity.
- for compressors with modulating capacity-control, the compressor operates in continuous unload/load.

## **19** Condensation control

Condensation can be performed in the following modes:

- ON/OFF linked to compressor operation (without pressure transducers)
- ON/OFF or modulating linked to reading by the pressure transducer (if the high pressure transducers were enabled)
- ON/OFF or modulating linked to reading by the battery temperature probes (if the battery temperature probes were enabled)

Employed Inputs:

Condensing pressure probe

Condenser coil temperature probe

- Outputs used:
- Fan 1
- Fan 2
- Speed control for fans AOUT 1

Employed Parameters:

- Selection of condensation control None /pressure/temperature
- Condensation set point
- Condensation band
- Number of fans
- Enable prevent function
- Prevent threshold
- Prevent differential
- Output voltage for inverter minimum speed
- Output voltage for inverter maximum speed
- Inverter speed-up time

## 19.1 ON/OFF condenser control linked to compressor operation

Fan operation will solely depend on compressor operation: Compressor OFF = fan OFFCompressor ON = fan ON

## 19.2 ON/OFF condenser control linked to the pressure or temperature sensor

Fan operation depends on compressor operation and on the value read by the pressure or temperature sensors according to a set point or to a band. When the pressure/temperature is lower than or equal to the set point, all fans are OFF, but when the pressure/temperature rises to set point + band, all fans are ON.

### 19.3 Modulating condenser control linked to the pressure or temperature sensor

With this type of condensation, the fans will be controlled through a 0/10 V analogue output, in proportion to demand by the pressure/temperature sensors. If the lower limit of the ramp is greater than 0 V, there will not be a proportional straight line, but, as in the first section of the graph, it will be below the set point-diff. by one step.

## 19.4 Prevent function

This function can be selected under the constructor password, and is used to prevent circuits shutting down due to high pressure. With the compressor ON, when this threshold is reached, the compressor is capacity-control forced until pressure returns to below the set point - of a settable differential. With the compressor OFF, when this threshold is reached, the fans are capacity-control forced until pressure returns to below the set point - a settable differential.

# 20 Defrosting control for water/air machines

#### Employed Inputs:

- battery B3 temperature (can be used as a pressure switch)
- high pressure B7
- Input for defrosting pressure switch 1

#### Employed Parameters:

- Inputs used for defrosting
- Type of defrosting (simultaneous / separate/independent)
- Type of defrosting start and finish (compressor behaviour)
- defrosting start set point
- defrosting stop set point
- Defrosting delay time
- Maximum defrosting time
- Type of compressor operation during the refrigerating cycle reversing stage.
- Drip-off time

Outputs used:

- Compressor 1
- Cycle reversing solenoid-valve 1
- Fan.

## 20.1 Types of defrosting

#### Simultaneous

Only one circuit has to request entering the defrosting cycle for all circuits to forcibly enter defrosting. Circuits which do not need to defrost (temperature above defrosting stop set-point) stop and wait. As soon as all circuits finish defrosting, the compressors may restart on heat pump operation.

#### Separate

The first pCO unit requesting defrosting begins to defrost, the other units - even if they request defrosting - wait (the heat pump continues to operate) until the first one finishes defrosting. All the units sequentially complete their defrosting cycle.

#### Independent

The units can start defrosting at random, independently of each other. In this way, there may be several machine starting to defrost simultaneously.

## 20.2 Type of end and start defrost

Defrosting can be managed either by the coil temperature probe or the high pressure probe; the user can choose, on the screen, one of the two probes. The compressor can have four different types of behaviour in connection with start/end of defrosting. This makes it possible to protect the compressor against sudden cycle reversing, if necessary. Times are not considered in these compressor power-downs and power-ups.

- None: The refrigerating cycle is reversed at inlet/outlet to/from the defrosting cycle occurs with the compressor ON.
- Start of defrosting: The compressor is powered down by the reversal of the refrigerating cycle only at the inlet of the defrosting cycle.
- End of Defrosting: The compressor is powered down by the reversal of the refrigerating cycle only at the outlet from the defrosting cycle.
- Start/end of defrosting: The compressor is powered down by the reversal of the refrigerating cycle both at the inlet and outlet to/from the defrosting cycle.

## 20.3 Defrosting a circuit with time/temperature control

If the battery temperature/pressure remains below the defrosting start set-point for a cumulative time equal to defrosting delay time, the circuit in question enters a defrosting cycle. the system's refrigerating capacity reaches maximum value the refrigerating circuit is reversed with the 4-way valve the fan in question goes OFF (if pressure probes are present)

The circuit leaves the defrosting cycle due to temperature/pressure (if battery temperature exceeds the defrosting stop set point) or due to maximum time if the defrosting cycle exceeds the set maximum time threshold.

## 20.4 Defrosting a circuit with time/pressure switches control

The control is exactly the same, the only difference is the fact that the temperature/pressure is no longer counted, but rather the status of the pressure switches.

## 20.5 Operation of fans during the defrosting stage

The fans are usually OFF during the defrosting cycle. They are activated only if the pressure probes were enabled and pressure exceeds the prevent threshold - in this way the unit is prevented from going into high pressure alarm status.

# 21 Free Cooling Control

#### Inputs used

- Water temperature at evaporator outlet
- Water temperature at inlet of Free Cooling battery
- External air temperature

#### Parameters used

- Type of unit
- Number of units
- Type of condensation
- Number of fans
- Free Cooling valve type
- Free Cooling type control
- Integration time
- Control set point
- Control setpoint offset
- Minimum Free Cooling Delta
- Maximum Free Cooling Delta
- Free Cooling Control differential
- Maximum threshold for Free Cooling valve opening
- Minimum threshold for condensation speed controller
- Free Cooling antifreeze threshold
- Compressor activation delay

#### Outputs used

- Condenser fans
- Condensation fans speed controller
- Free Cooling ON/OFF valve
- Free Cooling 3-way valve

## 21.1.1 Description of operation

Free Cooling control makes it possible to exploit the temperature conditions of external air to facilitate cooling use water. To this end, a heat exchanger is supplied. If necessary, a certain quantity of water is returned to this exchanger by the system, deviated via an appropriately commanded valve.

The favourable conditions of outside air cause the water to cool beforehand, and, therefore activation of the cooling devices is delayed.

Free Cooling is available in the air/water unit in the internal Free Cooling mode only. i.e. with the Free Cooling battery housed inside the machine near the condensation battery/ies, with which its shares control of the condensation fan/s.

## 21.2 Free Cooling activation condition

The entire Free Cooling procedure is based on a relationship between the temperature value measured by the external temperature probe, and the temperature value measured by the temperature probe located at the input of the Free Cooling heat exchanger and the set Free Cooling delta.

External T. < Free Cooling Input T. - Min. Delta Freecooling

If this condition is true, the freecooling function will be enabled, by activating/deactivating the dedicated devices.

## 21.3 Free Cooling Thermostat

Free Cooling control exploits the calculated control set point values (taking into account any compensation) and the set Free Cooling control differential. The control is based on the water temperature measured by the probe located at the evaporator outlet, considering the effective supply of cold of the Free Cooling exchanger according to the different external temperature conditions.

Two different control modes can be selected: proportional, proportional + integral - the integration constant must be set in the latter case.

The set point for thermostatic control of Free Cooling will be determined according to the nominal value of the temperature of the water you wish the unit to produce. Depending on the type of control adopted for the compressors (inlet – outlet), as the temperature references are different, two distinct control graphs will be identified. In machines controlled output with a neutral zone, the Free Cooling control set point will correspond to the control set point of the compressors.

Free Cooling Set point = Compressors set Point

The proportional control band will be equally distributed at the sides of the set point. The proportional band will be equally distributed on both sides of the set point. In units with inlet control and proportional band, the freecooling control set point will use an offset from the compressor control set point to compensate for the presence of the evaporator coil.

Free Cooling Set point = Compressors Set-point - Offset

The proportional control band will be equally distributed at the sides of the set point. In the Free Cooling control band, the activation thresholds for dedicated devices (e.g. valves and fans or speed variators) will be calculated in different ways according to the type of selection.

As the fans and/or speed variators are shared by Free Cooling control and condensation control, if one or more compressors in a given refrigerating circuit is/are enabled, priority will be given to condensation control to protect the circuit itself.

The Free Cooling valve will, in any event, be maintained fully open to provide as high as possible a thermal yield even at minimum ventilating capacity.

To optimise Free Cooling performance during the machine start transients and in steady state operating situations, a by-pass time is applied for thermostatic control of the compressors.

The purpose of this time is to delay the activation of the compressors in order to give Free Cooling sufficient time to reach the steady state conditions and take the machine's yield to nominal value. Only after this time has elapsed, and with the main thermostat dissatisfied, the compressors are commanded to operate. If time is set to 0, the function will be disabled. While the unit is operating, the same parameter is used by Free Cooling control to reassess the machine's working conditions according to the value measured by the external temperature probe. A further temperature delta should be set. This identifies a second threshold below which the yield of the Free Cooling battery is so high that it can fully satisfy the system's thermal load solely through combined operation of value and fans.

If the compressors are ON, the external temperature falls below "maximum delta" set according to the following relation:

External T. < Free Cooling Input T. - Free Cooling "Maximum Delta"

and this condition continues for a continuous time period equal to the set by-pass time for the compressors. When this time has elapsed, the compressors will be commanded to OFF followed by a changeover to pure Free Cooling operation to satisfy load requirements with minimum use of energy. When the by-pass time for thermostatic control of the compressors has again elapsed, the requests will be re-assessed.

An antifreeze threshold is specified. It is based on the temperature value of external air to protect the heat exchanger when operating in a cold environment. If the temperature of external air is lower than the set threshold, the valve controlling water flow inside the Free Cooling exchanger will be commanded to open, and the main circulation pump will be enabled (if OFF). This pump moves the fluid and prevents the interior of the exchanger from freezing.

If the valve is a 0-10V type, the degree of opening will depend on the unit's operating status.

- with the unit off the valve will open to 100% of capacity
- with the unit on the valve will open to 10% of capacity

If the valve is of the ON/OFF type, it will always open to maximum value irrespective of the unit's operating mode.

The entire procedure will finish as soon as the external air temperature reaches a fixed hysteresis of 1.0°C with respect to the set threshold.

### 21.4 Free Cooling disabling conditions

There are two main causes of the closure of the Free Cooling valve: the first depends on the external temperature conditions, and the second on thermostatic demand. The freecooling valve will be closed if the freecooling conditions are no longer present

External T. < Free Cooling Input T. - (Free Cooling Delta) + 1.5°C

The Free Cooling valve will close if the Free Cooling thermostat is satisfied. For system safety, the reading of the water temperature probe a the evaporator outlet will be checked. According to the set thresholds, the following will be processed: an antifreeze pre-alarm, which will enable any post-heating heaters and totally disable the Free Cooling devices; and an antifreeze alarm which will totally disable the unit. Other system safety devices : serious alarm from digital input, circulation pump thermal cutout, failed control probe, failed antifreeze control probe, evaporator flow-switch alarm, phase monitor alarm. These safety device will totally disabled the unit, and, therefore, stop the Free Cooling control.

## 21.5 Free Cooling ON/OFF valve

#### 21.5.1 Proportional control

If temperature conditions favour Free Cooling control, the Free Cooling ON/OFF valve will be activated as soon as temperature exceeds the activation threshold of the individual step, identified by a temperature value of:

Control Set point - Free Cooling Differential + 5.0% Free Cooling Differential

The step amplitude is fixed at 5.0% of the set Free Cooling control differential.

#### 21.5.2 Proportional + integral control

If temperature conditions favour Free Cooling control, the Free Cooling ON/OFF valve will be activated as soon as temperature exceeds the activation threshold of the individual step, identified by a temperature value of:

Control Set point + 5.0 % Freecooling differential

The step amplitude is fixed at 5.0% of the Free Cooling control differential.

## 21.6 Free Cooling ON/OFF valve with stepped condensation

### 21.6.1 Proportional control

Here is an example of Free Cooling control with ON/OFF valve and three condensation steps.

The ON/OFF valve activation step will, in any case, be positioned in the first part of the control differential and will have an amplitude of 5.0% of the said differential. The activation steps of the condensation fans will be positioned proportionally inside the Free Cooling control differential. To calculate the amplitude of each step, use the following relation:

Step amplitude = <u>Free Cooling Differential</u> (Number of Master fans X number of cards)

It is assumed that all the circuits controlled by the pCO cards making up the system are equivalent and that the number of controlled devices is the same.

#### 21.6.2 Proportional + integral control

Here is an example of Free Cooling control with ON/OFF valve and three condensation steps.

The devices, whether they are valve or fans, will be activated in the second half of the control differential through the effect of the integrating control. Their activation will be tied to the set integrating constant: the slower it is, the greater the value attributed to the specific parameter.

The amplitude of the valve control step will be 5.50% of the said control differential.

The amplitude of the fan control steps will be calculated according to the following relation:

Step amplitude = <u>Free Cooling Differential</u> (Number of Master fans X number of cards)

It is assumed that all the circuits controlled by the pCO cards making up the system are equivalent and that the number of controlled devices is the same.

## 21.7 Free Cooling ON/OFF valve with inverter controlled condensation

21.7.1 Proportional control

The ON/OFF valve activation step will, in any case, be positioned in the first part of the control differential and will have an amplitude of 5.0% of the said differential. The proportional ramp for piloting the analogue control output of the condensation inverter will be calculated on the entire control differential. If necessary, Value 0-10 Volt can be further limited downward according to the minimum output voltage value set on the screen. All proportional outputs relating to the different units of the system will be piloted in parallel

The devices, whether they are valve or fans, will be activated in the second half of the control differential through the effect of the integrating control. Their activation will be tied to the set integrating constant: the slower it is, the greater the value attributed to the specific parameter. The amplitude of the valve control step will be 5.50% of the said control differential. All proportional outputs relating to the different units of the system will be piloted in parallel

## 21.8 0-10 Volt Free Cooling ON/OFF valve

The Free Cooling valve is proportionally commanded in a different way depending on whether condensation control is in steps or by inverter. The control diagrams of the two different situations are shown below.

## 21.9 0-10 Volt Free Cooling ON/OFF valve with stepped condensation

21.9.1 Proportional control

The proportional control ramp of the Free Cooling valve will be calculated inside the first activation step of the condensation fans. In this way, when the first fan is enabled, the valve will be completely open, and, therefore, water flow in the Free Cooling exchanger will be at maximum level. The activation steps of the condensation fans will be positioned proportionally inside the Free Cooling control differential. To calculate the amplitude of each step, use the following relation:

Step amplitude

Free Cooling Differential

(Number of Master fans X number of cards)

It is assumed that all the circuits controlled by the pCO cards making up the system are equivalent and that the number of controlled devices is the same.

### 21.9.2 Proportional + integral control

The devices, whether they are valve or fans, will be activated in the second half of the control differential through the effect of the integrating control. Their activation will be tied to the set integrating constant: the slower it is, the greater the value attributed to the specific parameter. The proportional control ramp of the Free Cooling valve will be calculated inside the first activation step of the fans. In this way, when the first fan is enabled, the valve will be completely open, and, therefore, water flow in the Free Cooling battery (exchanger) will be at maximum level. The activation steps of the fans will be positioned proportionally inside the Free Cooling control differential.

To calculate the amplitude of each step, use the following relation:

Step amplitude = <u>Free Cooling Differential</u> (Number of Master fans X number of cards)

It is assumed that all the circuits controlled by the pCO cards making up the system are equivalent and that the number of controlled devices is the same.

## 21.10 0-10 Volt Free Cooling valve with inverter controlled condensation

21.10.1 Proportional control

The control proportional ramp of the Free Cooling valve will be calculated inside the area determined by the thresholds: Control Set point -Free Cooling Differential/2 Control Set point -Free Cooling Differential/2 + valve maximum opening % Threshold

The control proportional ramp of the condensation inverter will be calculated inside the area determined by the thresholds: Control Set point -Free Cooling Differential/2 + inverter speed minimum % Threshold Control Set point + Free Cooling Differential/2

The start/end points of the two control ramps can be modified at the user's discretion by varying the value of the thresholds (see graph) as a percentage of the value of the set Free Cooling differential.

For the Free Cooling valve, the setting field ranges from 25 to 100% of the differential.

For the condensation inverter, the setting field ranges from 0 to 75% of the differential.

| Example  |            |                |
|--|------------|----------------|
| Control setpoint   | 12.0°C     |                |
| Free Cooling Differential  | 4.0°C      |                |
| Free Cooling valve % threshold   | 40%        |                |
| Condensation inverter % threshold:   |            | 80%            |
| Proportional area for control of Free Cooling valve $=$                              |            | 10.0 ÷ 11.6 °C |
| Control Set point - Free Cooling Differential/2 =                                    | 10.0°C     |                |
| Maximum % threshold for valve opening $=$  | 1.6°C      |                |
| Proportional area for control of condensation inverter $=$                           | 13.2 ÷ 1   | 6.0 ºC         |
| Control Set point - Free Cooling Differential/2 =                                    | 10.0°C     |                |
| Control Set point - Free Cooling Differential/2 + inverter speed minimum % Threshold | d = 13.2°C |                |

### 21.10.2 Proportional + integral control

The devices, whether they are value or fans, will be activated in the second half of the control differential through the effect of the integrating control. This activation will be constrained by the set integrative constant. The greater the value assigned to the integration time, the slower the system's response.

## 22 Control algorithm for Bitzer screw compressors

Carel developed a second Algorithm according to the Bitzer specifications to manage and protect their compressors. By setting the "Compressor Type" parameter to "Bitzer Steps" or "Bitzer Stepless", the compressor's control algorithm is automatically set according to their specifications.

With this kind of compressor, it is best to use hardware with SSR outlets to guarantee a long control life, because the CR4 valve switchings in the Steps and CR3 and CR4 in the Stepless are very high.

In this case, the hardware codes become PC01004CM0, PC03002AM0 or PC03002BM0 and for the connection table (chpt. 7) see the Bitzer column.

The Bitzer management is integrated into the software application and keeps the suction and outlet pressure conditions under control, optimising the compressor fridge capacity both via the management of the control valves in step mode and in continuous control mode.

On the basis of the refrigerant selected via the "Refrigerant" parameter, the Bitzer management considers the compressor's application limits, that is, the enveloping of the pressures according to the Bitzer specifications. With this compressor, only the R407c, R22, R134a refrigerants can be selected.

This enveloping of the application limits.

## Diagramma di applicazione

For each refrigerant, the polygon changes shape according to the following levels in the table.

#### **Absolute pressures**

| Polygon<br>points | W     | ith or | R22<br>without EC | R134a ECO<br>With or without ECO |       |     | R407C<br>With or without ECO |      |       |     |      |      |

| max c             |       |        | 60,0              | 24,3                             |       |     | 65,0                         | 18,9 |       |     | 60,0 | 25,3 |
| max o             | 17,5  | 8,5    |                   |                                  | 20,0  | 5,7 |                              |      | 17,5  | 8,2 |      |      |

## 22.1 Protection

Apart from the standard protection with the high and low pressure switches, the heat windings, the oil differential pressure switch and the Bitzer management keeps the compressor away from dangerous pressure conditions. Furthermore, the Bitzer management controls the frequency of the compressor thrusts, including in the case of loss of power, and minimum on/off times. And more than this:

### 22.1.1 Zone A

• Above the maximum condensation limit (max. c)

The compressor is stopped immediately.

### 22.1.2 Zone B

The maximum capacity of the compressor is limited to 75%, and this condition is allowed for a maximum of one minute; if after one minute, the pressure level is not yet within the polygon, the compressor is stopped immediately.

## 22.1.3 Zone F

NORMAL WORKING

The maximum capacity of the compressor is unlimited (available up to 100%), but this condition is allowed for a maximum of one minute; if after one minute, the pressure level is not yet within the polygon, the compressor is stopped immediately.

START-UP

The compressor is switch-on with the power to 25% for 10s in order then passing to 50% and remains in this state for any thermostatic demand. In this zone the compressor can remain active if after 70s min difference HP-LP is greater then 1 bar and if after 370s the same difference is greater then 3 bars. If one of these conditions doesn't respect the compressor is switched-off then it is turned-on when protection times expired. This last procedure is repeated for 3 attempts. The compressor is stopped if after third attempts it stills into zone F. During the compressor restart the unit status, present in the main mask, will display "RESTART". This type of protection is active when the compressor, in same starting, is not entered in zone C.

## 22.1.4 Zone C

#### • Polygon compressed between 1-2-3-4-5-6 points

Inside this zone, the compressor's capacity is unlimited and is managed solely according to the requests made.

## 22.1.5 Zone D

### Polygon compressed between points 6-7-10-1

The maximum capacity of the compressor is limited to 75% without any time limit. In this case, the compressor is not compressed.

### 22.1.6 Zone E

#### Polygon compressed between points 7-8-10-1

The maximum capacity of the compressor is limited to 50%, and this condition is allowed for a maximum of 10 minutes; if after 10 minutes, the pressure level is not yet within the polygon, the compressor is stopped immediately.

## 22.1.7 Zone G

### • above max. o

If the limit is reached when already operational, the compressor is stopped immediately.

On the contrary, only at the start, above this limit, the maximum capacity of the compressor is limited to 50% and this condition is allowed for a maximum of 5 minutes.

If after 5 minutes from the start, the pressure level is still not inside the polygon, the compressor is stopped immediately, otherwise all the above protections are applied.

#### 22.1.8 High delivery temperature alarm

The alarm condition that can be set via relative setpoint and hysteresis, stops the compressor immediately. The default level is 120°C.

## 22.2 Start up procedure

On start up, the compressor capacity is limited to 25% for 10 seconds. After 10 seconds, the compressor is controlled according to the enveloping of the application limits and depending on the requests made.

#### 22.2.1 Part winding

The part winding start up is handled directly by Macroblocco in line with Bitzer specifications.

## 22.3 Capacity control

Via the "Compressor Type" parameter, the kind of capacity control can be selected, that is, stepped if "Bitzer Steps" or modulating if set at "Bitzer Stepless".

#### 22.3.1 Step control

By choosing "Bitzer Steps", the compressor capacity varies between 0% (compressor off), 25%, 50%, 75% and 100% (maximum load) depending on the requests made. Under every kind of condition, the maximum capacity is limited according to application enveloping even in the case where 100% is requested. There is no delay in the stepped control on the capacity change.

#### 22.3.2 Stepless control

By choosing "Bitzer Stepless", the compressor capacity varies between 0% (compressor off), and is modulated from 25% to 100% (full load) depending on the requests made. Under every kind of condition, the maximum capacity is limited according to application enveloping even in the case where 100% is requested. In all condition the maximum cooling capacity is limited according to the envelop application limits, even in case of cooling demand is requiring 100%.

#### 22.3.3 Economiser and liquid injection

The economiser or liquid injection valve is controlled by the relative setpoints and hysteresi

# 23 Alarms

Alarms are divided into three categories:

- signal-only alarms (signal on the display, buzzer, alarm relay)
- circuit alarms (deactivate only the corresponding circuit, signal on the display, buzzer, alarm relay)
- serious alarms (deactivate the entire system, signal on the display, buzzer, alarm relay)

## 23.1 Serious alarms

- "No water flow" alarm
- Serious alarm from digital input
- Phase monitor alarm
- Pump thermal cutout

## 23.2 Circuit alarms

- High pressure/pressure switch alarm
- Low pressure alarm
- Compressor thermal overload alarm
- Oil differential alarm
- Fan thermal overload alarm
- Unit disconnected from network alarm
- Pressure differential alarm
- Evaporator antifreeze alarm
- High current alarm

## 23.3 Warning only alarms

- Unit maintenance alarm
- Compressor maintenance alarm
- Clock card faulty or disconnected alarm
- High voltage alarm

## 23.4 Pressure differential alarm management

Inputs used

- Low pressure transducer
- High pressure transducer
- Parameters used
- Enable alarm
- Pressure differential set-point
- Alarm activation delay

Outputs used

- General alarm relays
- All compressor outputs

#### 23.4.1 Description of operation

The alarm is based on the differential between high and low pressure probe readings If this differential drops below the set differential value, the alarm is signalled and the compressor is powered down, according to the set delay.

## 23.5 Antifreeze control

Inputs used:

- Water temperature at evaporator outlet
- Water temperature at condenser outlet

Parameters used:

- Enable evaporator outlet probe
- Enable condenser outlet probe
- Antifreeze heater setpoint
- Antifreeze heater differential
- Antifreeze alarm set point
- Antifreeze alarm set point
- Forcing of main pump due to antifreeze alarm
- Outputs used :
- Antifreeze heater
- General alarm relays
- All compressor outputsMain circulation pump

#### Description of operation

Every pCO unit is able to manage antifreeze control providing the water temperature probe at evaporator/condenser outlet is connected and enabled according to the type of unit being controlled.

Antifreeze control is always enabled, even if the machine is OFF, both in summer and winter operating modes. For type 5 machines with reversing of the water circuit, the antifreeze control always controls water temperature at evaporator outlet, shifting control to the evaporator or condenser according to the operating mode (summer-winter).

The antifreeze alarm is a circuit alarm, in multi-board systems, and will cause the total shutdown of the unit when all the circuits are in antifreeze mode. A control parameter is provided, which enables you to select whether to keep the main circulation pump ON or OFF in the event of an antifreeze alarm This will have effect only when all the circuits are in antifreeze status, otherwise the pump will remain on. In units with the freecooling coil, in the event of antifreeze alarms the 4-way valve will be closed.

The heater activation is displayed on unit status of main mask.

## 23.6 pCO alarms table

| Code | Alarm description                | OFF<br>Compressors | OFF<br>Fans | OFF<br>Pump | OFF<br>System | Reset     | Delay    | Signal  |
|------|----------------------------------|--------------------|-------------|-------------|---------------|-----------|----------|---------|
| 011  | Serious Alarm                    | *                  | *           | *           | *             | Manual    |          | Mst/Slv |
| 012  | Phase Monitor Alarm              | *                  | *           | *           | *             | Manual    |          | Mst/Slv |
| 018  | Evaporator Pump thermal Cutout   | *                  | *           | *           | *             | Manual    |          | Mst     |
| 019  | Condenser Pump thermal Cutout    | *                  | *           | *           | *             | Manual    |          | Mst     |

## 24 Alarm log

The alarm log can store the standard chiller's operating state when alarms are generated or at particular times. Each record represents an event that can be displayed from the list of all the events available in the memory. The log is used to resolve problems and faults as it represents a "snapshot" of the installation at the moment the alarm was activated, and may suggest the possible causes and solutions to the faults. There are two kinds of log in the program, the STANDARD log and ADVANCED log.

## 24.1 Standard log

The pCO\* boards' considerable buffer space means events can be saved in the STANDARD log, which is always available on the various boards. If there is no clock card (optional extra on pCO1, built-in feature on pCO2 and pCO3), the STANDARD log just gives the alarm code. The maximum number of events that can be logged is 100. Once the hundredth alarm is reached, i.e. the last available slot in the memory is taken, the oldest alarm (00) is erased as it is overwritten with the next alarm, and so on for subsequent events. Logged events cannot be deleted by the user unless installing factory settings. The STANDARD log screen can be called up by pressing the MAINTENANCE key, and looks like this:

| +   |        |        | +      |
|-----|--------|--------|--------|
|     |        |        | 7 A2   |
| ALO | 00 00: | 00 00/ | /00/00 |
|     |        |        | 000.0  |
| HP  | 000.0  | LP     | 000.0  |
|     |        |        |        |

For each alarm, the following data are stored relating to the standard chiller at the time of the alarm:

- alarm code
- Time;
- Date;
- chronological number of the event (0...99)

The chronological event number indicates the "seniority" of the event with respect to the 100 available storage slots. The alarm with number 00 is the first to occur after the STANDARD logs are enabled, and hence the oldest.

If you move the cursor onto the chronological number, you can run through the alarm log, from 0 to 99, using the arrow keys.

For instance, if you are on position 00, pressing the down arrow will not take you anywhere.

If 15 alarms have been logged, for instance, and you are on position 014, pressing the up arrow will not take you anywhere.

## 24.2 Advanced log

Events are logged on the 1MB or 2MB memory expansion module, which is a permanent appendix to the board. Advantages and features are listed below:

- Event-based log: a typical event-based log is the alarm log. When an alarm occurs, the alarm generated is stored along with significant data (temperatures, pressures, setpoints etc.).
- Time-based log: a typical event[sic! probably time]-based log is the temperatures/pressure log. Temperature and pressure values are stored at regular intervals.
- Log log: this is the log of the last alarms/temperatures/pressures stored before a serious alarm. Unlike data stored in the event- and time-based logs, these data are not overwritten when the memory is full.
- You have the option of choosing the values to be saved at any time as well as the method used to save them. Using the "WinLOAD" utility program, you can
  define the values to be saved and the method used to save them with the aid of a practical Wizard. WinLOAD does not need application software files as it can
  procure all the information required directly from the pCO\* board's resident application software.
- 1MB of dedicated FLASH memory. With this system, data are saved to the 1MB FLASH memory included in the memory expansion module (code PC0200MEM0 for pC02). By way of example, 1MB of memory can hold 5,000 alarm events with 5 values for each alarm, and 6 months of recording 2 values for instance, temperature and pressure saved every 5 minutes.
- Option of defining up to 7 different log configurations. Usually, each controller will have one alarm log and one log for control values (temperature/humidity/pressure) configured, in addition to a number of "log logs".
- Stored data can be consulted either via the (separate or built-in) LCD terminal or via a connected PC.
- "Black box" operating mode. The memory expansion module containing the logs can be removed from the controlled unit's pCO<sup>2</sup> and inserted in another pCO<sup>2</sup>, via which the stored data can be consulted. The host pCO<sup>2</sup> does not need to contain the same software as the original.
- Stored data reliability. Data are saved to a FLASH memory that does not need batteries, which are liable to run down. If previously stored data are not compatible with new software following an upgrade, all data are erased (you are prompted to confirm first).

### 24.3 List of alarm log codes

- AL:001 Unit No. 1 Offline
- AL:002 Unit No. 2 Offline
- AL:003 Unit No.3 Offline AL:004 Unit no. 4 Offline
- AL:011 Serious alarm from digital input
- AL:012 Phase monitor alarm

AL:216 Incomplete setup procedure on driver 2

## 25 Supervisor

The unit can be interfaced to a local or remote supervision/remote-assistance system. Between the pCO\* card accessories, an optional card is planned for serial communication via RS485 interface, supplied separately from the pCO\* card (for installation instructions for the serial communication optional cards, see installation manual of pCO\* card).

The software can handle the following supervision protocols:

- CAREL
- Modbus
- LonWorks (via special optional card)
- Trend (via special optional card)
- Bacnet (via external gateway or PCO-WEB)

If the serial communication values (serial address and communication speed) are correctly set, the parameters transmitted by the unit will be as shown on the following table. By setting the serial identification number to 0, the communication towards the supervision system is disabled. Follow the list of variables managed by the supervisor.

| 25.1.1 | Key |
|--------|-----|
|--------|-----|

| 25.1.1 | Key               |
|--------|-------------------|
| А      | Analogue variable |
| D      | Digital variable  |
| I      | Integer variable  |

| Input variable        | pCO 🗲 Supervisor                        |
|-----------------------|---|
| Output variable       | pCO $\rightarrow$ Supervisor            |
| Input/output variable | pCO $\leftarrow \rightarrow$ Supervisor |
|                       | Input variable<br>Output variable       |
